

React Day 3

Components

☐ what is components ?

components are nothing but small small part of website we see, for example in website we see some basic parts like header hero section footer, so what are they, they are nothing but the components.

The header is one component, as well as others are.

☐ How to make components ?

- making components is very simple
- make a new jsx file for example Header.jsx (make sure first letter should be capital)
- now in the Header.jsx file enter rafce and click tab button
- the component is created, make sure to have default export statement at last

☐ How to use components ?

- to use this component in, select components where we have to use it then use it like
- `<Header />` or `<Header></Header>` (make sure to import it first)

☐ What are the types of components ?

- there are basically two types of components are present 1. function based 2. class based
- we use function based components because it is easy to use and have its own profit

```
React-In-15-Days > Day3 > project > src > components > Header.jsx > ...
1  import React from 'react'
2  |
3  const Header = () => {
4    return (
5      <div>Header</div>
6    )
7  }
8
9  export default Header
```

The components are looks like this

☐ Types of Exports for React Components

a. **Default Export**

- i. most common for single components
- ii. we can export the component directly as default export
- iii. when to use this → when file contain single main components (one file == one component)
- iv. multiple nahi ho sakte ek file mein

```
jsx
// File: Header.js
function Header() {
  return <h1>This is the Header</h1>;
}
export default Header;

♦ Import:

jsx
// File: App.js
import Header from './Header'; // No curly braces, can name it anything
```

a. **Named Export**

- i. exporting components by name
- ii. when to use →
 - When **multiple components** are in the same file.
 - When you want to export multiple utilities from one module.

```
// File: Components.js
export function Header() {
  return <h1>This is the Header</h1>;
}

export function Footer() {
  return <h1>This is the Footer</h1>;
}

♦ Import:

jsx                                     Copy Edit

// File: App.js
import { Header, Footer } from './Components'; // Curly braces, name must match
```

c. Multiple Export

- i. When you want to **highlight one main component** but still export additional ones.

```
jsx                                     Copy Edit

// File: Components.js
export default function Header() {
  return <h1>This is the Header</h1>;
}

export function Footer() {
  return <h1>This is the Footer</h1>;
}

♦ Import:

jsx                                     Copy Edit

// File: App.js
import Header, { Footer } from './Components';
```

its not mandatory to import components, we can also export some variable like
export const key="ajkdh3545" like this

JSX

☐ what is jsx ?

- it is syntax extension for javascript that allows u to write html look like code inside the javascript code ?
- its long for is javascript syntax xml or javascript xml, but in official documentation there is no mention of that.
- there is confusion in the long form of the jsx , so in simple we called it syntax extension for javascript
