

React Day 15

◆ What is an API?

- API stands for Application Programming Interface.
- It is not a function, but a **set of rules or a bridge** that allows different software applications to talk to each other.

◆ Example:

Imagine you're at a restaurant:

- You (the user) want food (data).
- The waiter (API) takes your order and brings your food from the kitchen (server/database).

In programming:

- You (frontend code) want user data.
- The API sends a request to the server and returns user data as a response.

🔍 What is `use()` in React?

- `use()` is an experimental React feature.
- It allows you to "await a promise inside a component" (usually used in React Server Components or with `Suspense`).
- It works by suspending the component until the promise is resolved.

✦ So it's not an API in the sense of a web API like `fetch()` — it is a React feature to handle asynchronous data in a declarative way.

```

import React, { Suspense, use } from 'react';

const fetchData = fetch('https://dummyjson.com/users').then((res) => res.json());

const Use = () => {
  return (
    <div>
      <h3>Use API in React JS</h3>
      <Suspense fallback=<p>Loading...</p>>
        <Users usersResponse={fetchData} />
      </Suspense>
    </div>
  );
};

const Users = ({ usersResponse }) => {
  const userData = use(usersResponse);
  console.log(userData);

  return (
    <div>
      <h4>Users:</h4>
      <ul>
        {userData.users.map((user) => (
          <li key={user.id}>{user.firstName} {user.lastName}</li>
        ))}
      </ul>
    </div>
  );
};

export default Use;

```

- new feature in react 19
- use can handle promise and return data from promise
- we should use 'use API' with suspense
- use API can use to handle context API also
- use api reduce rerendering of component as compare to use effect
